

Get the right tools

First of all, the new plank needs to be checked under different light circumstances (also grazing light) to compare it with the condition of the existing floor (which needs to be properly clean), to make sure the colour and surface of the new plank is similar and will blend in. This can for example be done during different moments of the day, while the replacement plank is acclimatizing (note, this plank needs to be acclimatized a minimum of 1 week in advance to let the plank having air contact on all 6 sides to adapt to the surrounding RH%).

1. Remove the plank to be replaced.

Adjust the circular saw to the depth of the floorboard and cut the plank lengthwise along its center axis. Carefully make radial cuts from the central cut to the 4 corners of the plank, making sure not to cut or otherwise damage the adjoining planks.

Gently unclick the cut pieces of the damaged plank from the adjoining planks, one by one.

Clean the area from where you removed the plank. Tape also the moisture barrier, so its sealed again.

2. Prepare the replacement plank.

Adapt the new plank (the plank needs to be acclimatized in advance).
Adapt the short side : cut off the short end profile, the one with PrimeLoc.

Adapt the long side : cut off a part of the locking profile, on the opposite side of the AluLoc, so that there is no part of this profile that can block when you install the plank.

3. Prepare the installation of the new, adapted plank.

Install the adjusted plank : place a piece of laminate edging (0,6 mm) on the short side (where PrimeLoc was), and apply a bi-component glue that's still is elastic. This will give support to the area from where you removed PrimeLoc.

Apply also wood glue on the long side.

Click in the adjusted replacement plank.

Add weights and clean up excessive glue with BerryAlloc Wipes.

Leave to dry for 24 h.

That's it! Enjoy the final result.
